PSMC (Pairwise Sequentially Markovian Coalescent)

<-- present

Time (years)

past

THE PSMC

(Pairwise Sequentially Markovian Coalescent)

Estimates the **distribution of coalescence times** along the genome of a **single diploid** individual by looking at the pattern of **heterozygous sites**.

Finds the history of **population size changes** that best explains this pattern.

Requires

- Mutation rate
- Recombination rate
- Generation time

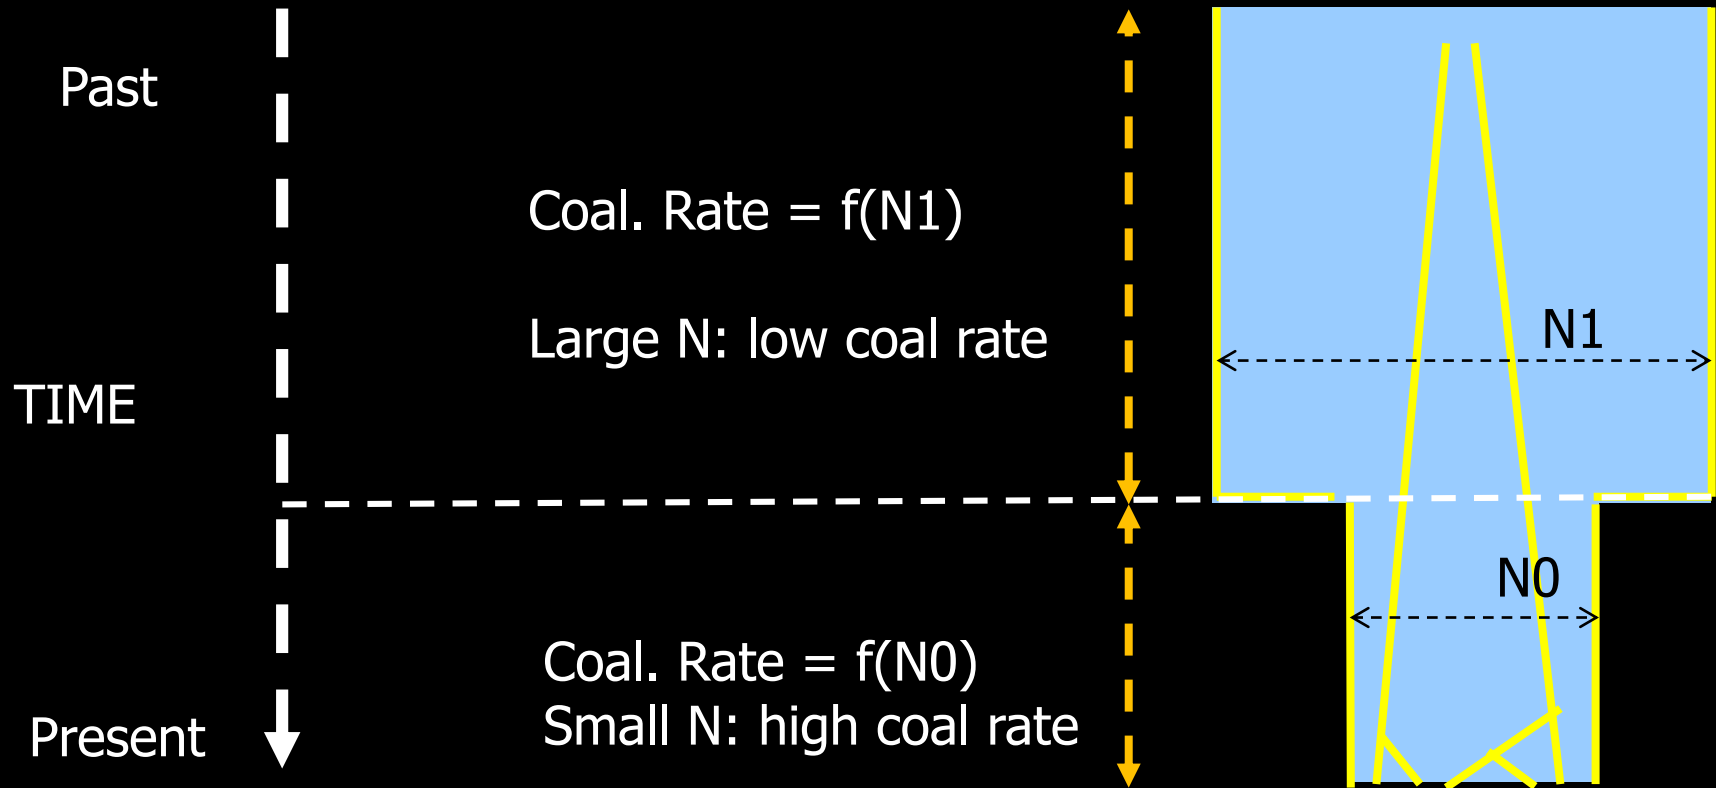

Assumes **panmixia** (no population structure / total isolation) in the **interpretation** step

Coalescence rates in panmictic populations:

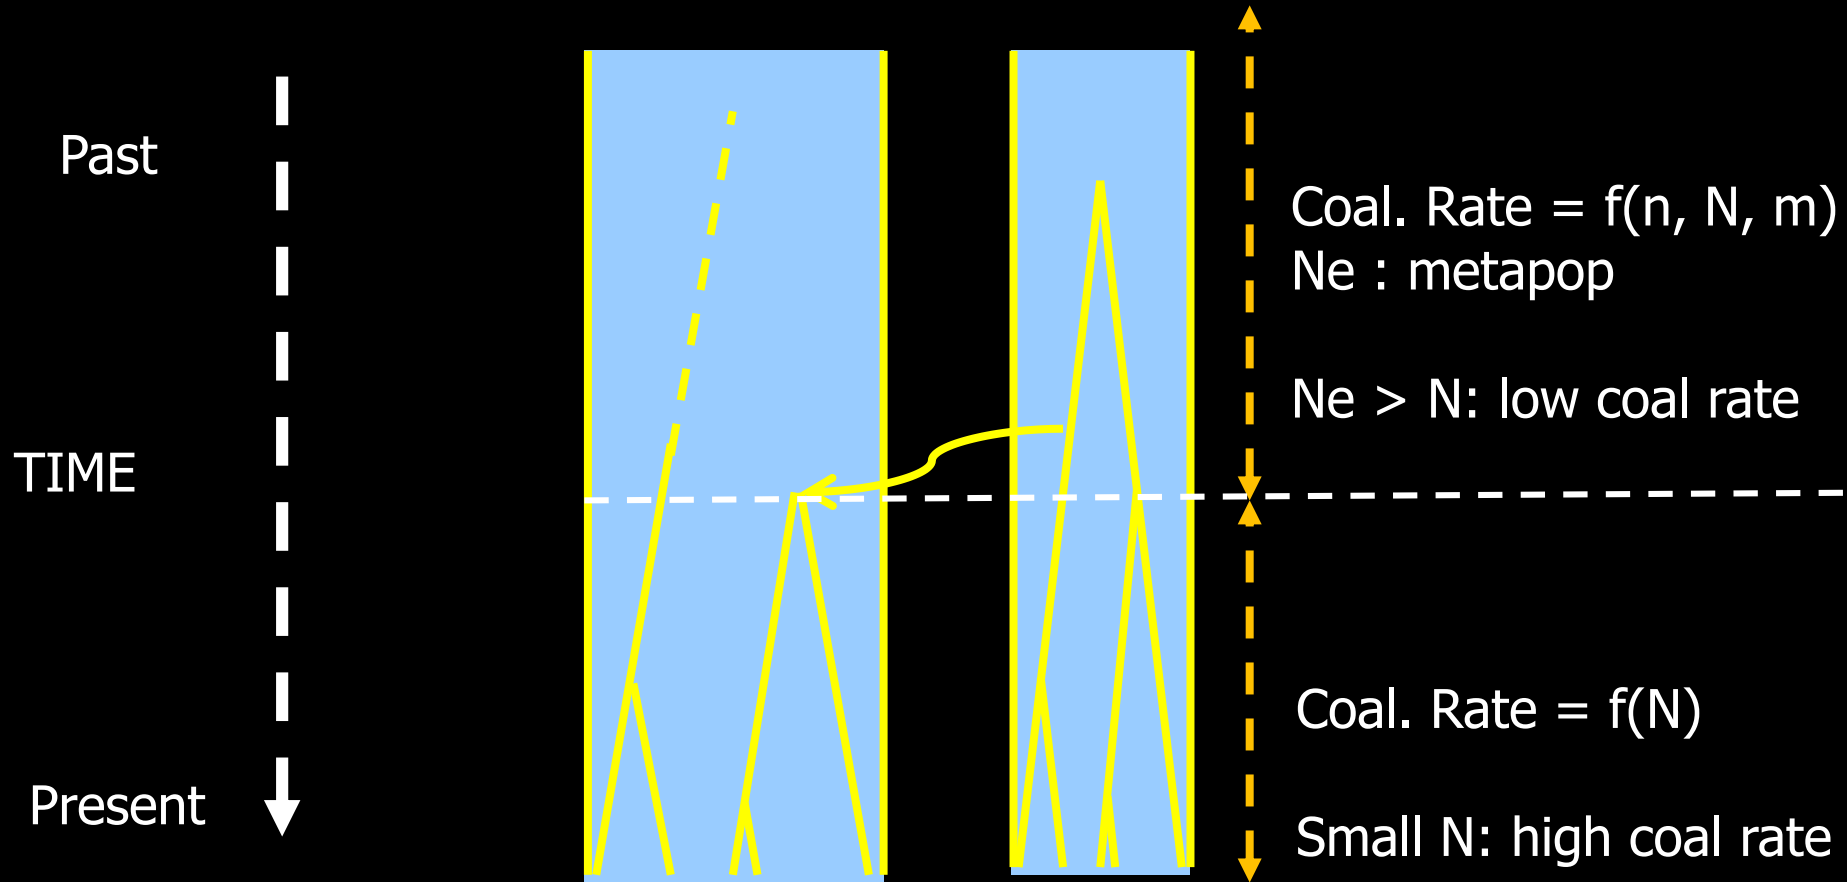

Coalescence rates in panmictic populations: with population size changes

If we can estimate variation in coalescence rate
we can thus estimate variation in N

Example : (Bayesian) Skyline plots, PSMC, MSMC, stairway plots

Departures from the panmictic model population structure

Population size change *versus* population structure

Did Our Species Evolve in Subdivided Populations across Africa, and Why Does It Matter?

Scerri et al. 2018

Trends in Ecology & Evolution

The IICR (inverse instantaneous coalescence rate)

The IICR can be seen as a (fictitious) history of population size change that will perfectly fit the distribution of coalescence times (T_2) that will be inferred from a single genome, even if the individual comes from a population that is not panmictic.

It is the inferred history IF the population is panmictic

Otherwise (population structure) this (fictitious) history is the IICR of that sample (IICR₂)

The IICR is the inverse of a coalescence rate, and thus is equivalent to a N_e in a panmictic population

$IICR = f(\Phi, [s], t)$ Φ = model parameters

SNIF: Structured Non-stationary Inferential Framework

- Inference of demographic parameters
- Differential Evolution as the optimization technique
- Distance used between IICR curves:

$$d(\text{IICR}_0, \text{IICR}_1) = \int_0^{\infty} |\text{IICR}_0(t) - \text{IICR}_1(t)| \cdot \text{pdf}_{\text{IICR}_1}(t) dt$$

- Implementation using Python SciPy library + D Programming Language for performance-sensitive parts

n = nb of islands
 M_0, M_1 , etc. Migration
 t_0, t_1, t_2 , etc. Time of change

components

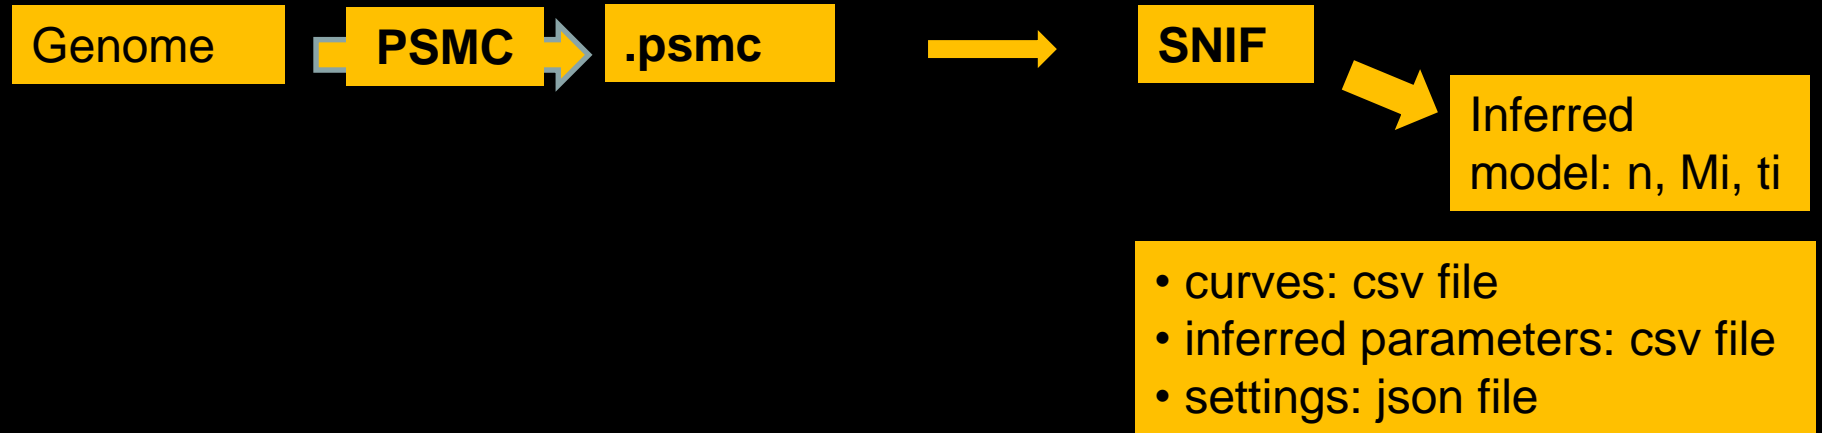

Summary (1/2)

- The PSMC method uses the genome of a single individual and produces a wavy curve that is a function of time
- This wavy curve corresponds to what we call the IICR (inverse instantaneous coalescence rate)
- Under panmixia the IICR is equivalent to an effective population size (N_e) → Interpretation 1
- Under population structure the same IICR can be interpreted in terms of changes in connectivity (assuming constant population size) → Interpretation 2
- It is possible to fit by hand model of population structure with a limited number of changes in connectivity

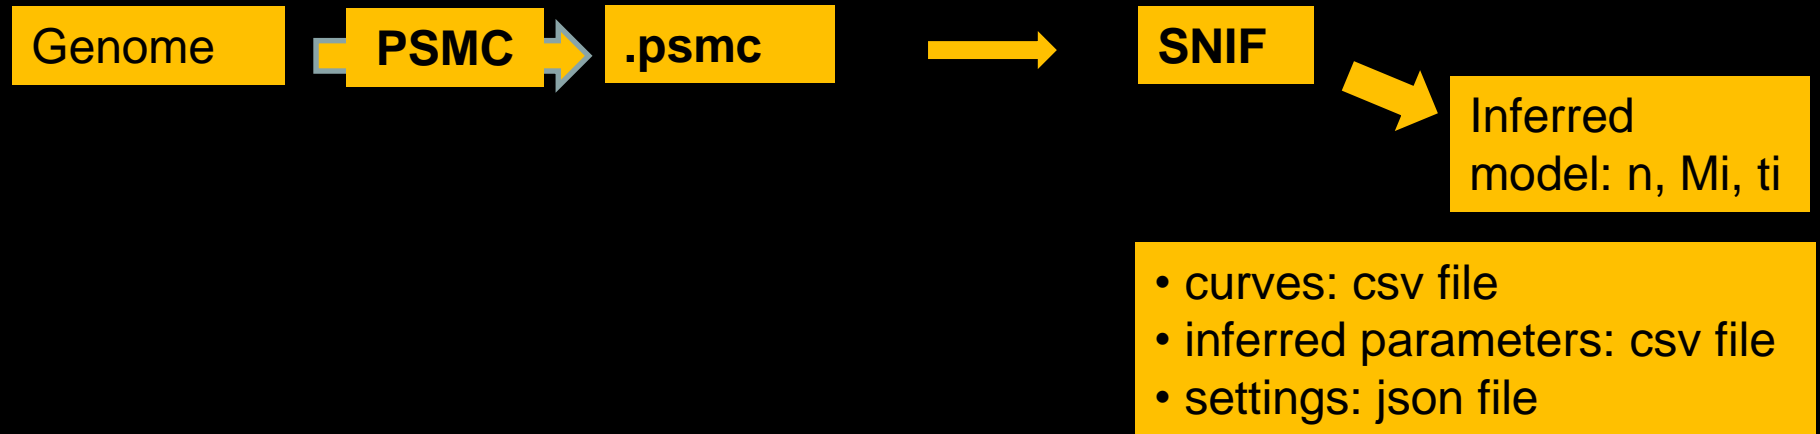

Summary (2/2)

- SNIF is a method that fits the **best n-island model** to a PSMC/IICR curve and infers the parameters of a non-stationary n-island model or “piecewise stationary n-island model”.
- We can infer (for a given number of components)
 - **The number of populations** (most methods assume that number and do not estimate it)
 - The **size** of the populations
 - The **times** at which gene flow (connectivity) changes
 - The values of **migration rates** (gene flow) for each of the components
- SNIF has been validated under very complex conditions using simulated data

- etc.

SNIF

SHOULD YOU BELIEVE THE INFERRED MODEL?

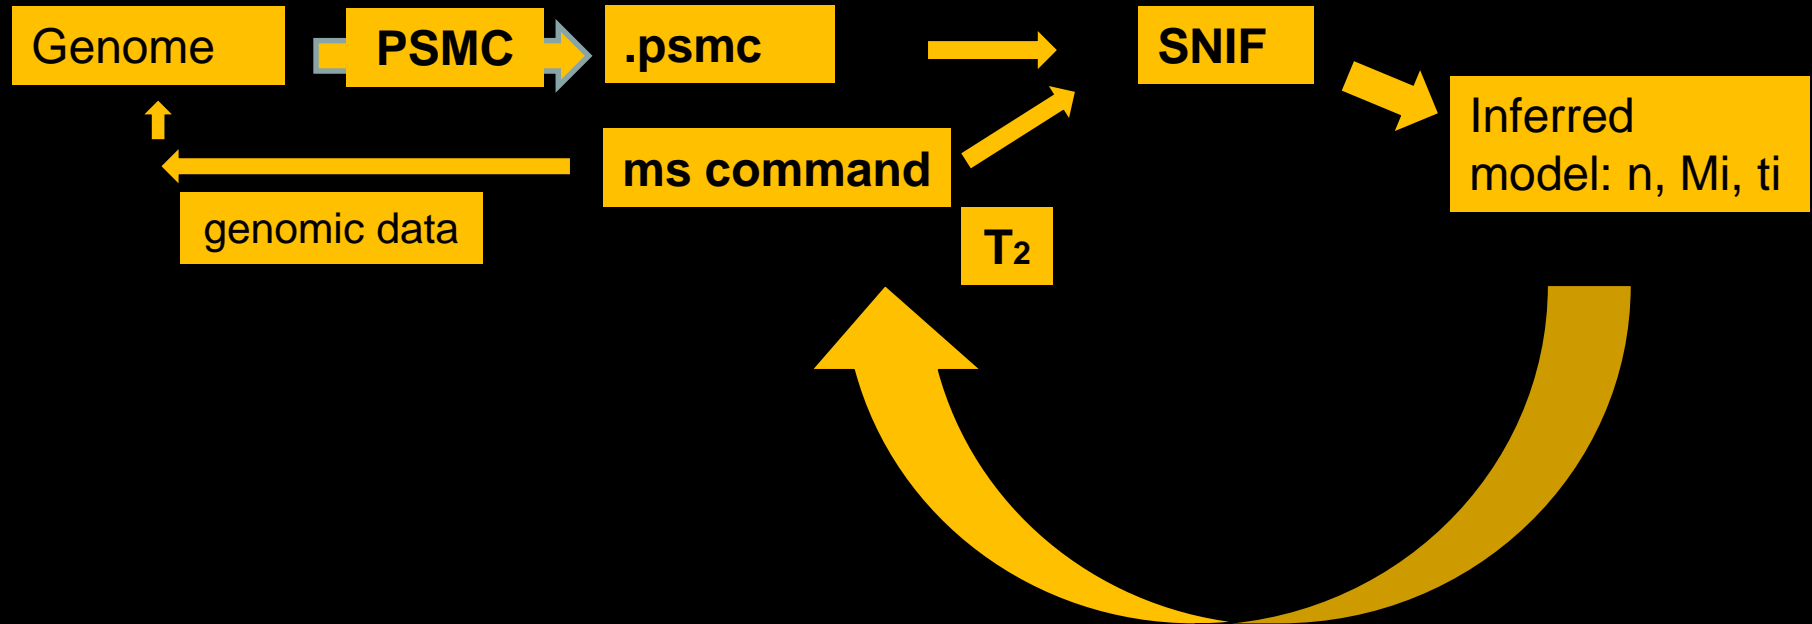

VALIDATION ?

1. Simulate data under the inferred model
2. Use the simulated data as input for SNIF
3. Compare the results of this newly inferred model to the model used as input
